## Compact matrix multiplication formulas

- Block matrix multiplication

$$
A\left(\begin{array}{ll}
B_{1} & B_{2}
\end{array}\right)=\left(\begin{array}{ll}
A B_{1} & A B_{2}
\end{array}\right) \quad A\left(\begin{array}{lll}
B_{1} & \cdots & B_{n}
\end{array}\right)=\left(\begin{array}{lll}
A B_{1} & \cdots & A B_{n}
\end{array}\right)
$$

$$
\binom{A_{1}}{A_{2}} B=\binom{A_{1} B}{A_{2} B} \quad\left(\begin{array}{c}
A_{1}^{\top} \\
\vdots \\
A_{m}^{\top}
\end{array}\right) B=\left(\begin{array}{c}
A_{1}^{\top} B \\
\vdots \\
A_{m}^{\top} B
\end{array}\right)
$$

- Both matrices split into blocks

$$
\begin{gathered}
\left(\begin{array}{ll}
A_{1} & A_{2}
\end{array}\right)\binom{B_{1}}{B_{2}}=A_{1} B_{1}+A_{2} B_{2} \\
\left(\begin{array}{lll}
A_{1} & \cdots & A_{k}
\end{array}\right)\left(\begin{array}{c}
B_{1}^{\top} \\
\vdots \\
B_{k}^{\top}
\end{array}\right)=A_{1} B_{1}^{\top}+\cdots+A_{k} B_{k}^{\top}
\end{gathered}
$$

## Vector product

- Definition

$$
\begin{aligned}
\mathbf{a} \times \mathbf{b}=[\mathbf{a}]_{\times} \mathbf{b} & =\left(\begin{array}{l}
x \\
y \\
z
\end{array}\right) \times\left(\begin{array}{l}
x^{\prime} \\
y^{\prime} \\
z^{\prime}
\end{array}\right)=\left(\begin{array}{c}
y z^{\prime}-z y^{\prime} \\
z x^{\prime}-x z^{\prime} \\
x y^{\prime}-y x^{\prime}
\end{array}\right) \\
{[\mathbf{a}]_{\times} } & =\left(\begin{array}{ccc}
0 & -z & y \\
z & 0 & -x \\
-y & x & 0
\end{array}\right)
\end{aligned}
$$

- Properties: bilinear, antisymmetric.
- Link with determinant

$$
\mathbf{a}^{\top}(\mathbf{b} \times \mathbf{c})=\left\lvert\, \begin{array}{lll}
\mathbf{a} & \mathbf{b} & \mathbf{c}
\end{array}\right.
$$

- Composition

$$
(\mathbf{a} \times \mathbf{b}) \times \mathbf{c}=\left(\mathbf{a}^{\top} \mathbf{c}\right) \mathbf{b}-\left(\mathbf{b}^{\top} \mathbf{c}\right) \mathbf{a}
$$

- Composition with isomorphism $M$

$$
(M \mathbf{a}) \times(M \mathbf{b})=|M| M^{-\top}(\mathbf{a} \times \mathbf{b}) \quad[M \mathbf{a}]_{\times}=|M| M^{-\top}[\mathbf{a}]_{\times} M^{-1}
$$

## RANSAC algorithm

## Triangulation

## Fundamental principle of stereo vision

- "Rectified" setup: common image plane, parallel camera motion

- In the coordinate frame linked to the camera:

$$
z=\frac{f B}{d}
$$

- $f=$ focal length, $B=$ baseline (distance between optical centers), $d=$ disparity

Goal
Given two rectified images, point correspondences and computation of their apparent shift (disparity) yield relative depth of the scene.

## Epipolar constraints

Rays from matching points must intersect in space

- The vectors $\overrightarrow{C x}, C^{\prime} \mathbf{x}^{\prime}$ and $T$ are coplanar. We write it in camera 1 coordinate frame: $\mathrm{x}, R \mathrm{x}^{\prime}$ and $T$ coplanar,

$$
\left|\mathbf{x} \quad T \quad R \mathbf{x}^{\prime}\right|=0
$$

which we can write:

$$
\mathbf{x}^{\top}\left(T \times R \mathbf{x}^{\prime}\right)=0
$$

- We note $[T]_{\times} \mathbf{x}=T \times \mathbf{x}$ and we get the equation

$$
\mathbf{x}^{\top} E \mathbf{x}^{\prime}=0 \text { with } E=[T]_{\times} R
$$

(Longuet-Higgins, Nature, 1981)

## Epipolar constraints

- $E$ is the essential matrix but deals with points expressed in camera coordinate frame.
- Converting to pixel coordinates requires multiplying by the inverse of camera calibration matrix $K$ : $\mathbf{x}_{\text {cam }}=K^{-1} \mathbf{x}_{\text {image }}$
- We can rewrite the epipolar constraint as:

$$
\mathbf{x}^{\top} F \mathbf{x}^{\prime}=0 \text { with } F=K^{-\top} E K^{\prime-1}=K^{-\top}[T]_{\times} R K^{\prime-1}
$$

(Luong \&Faugeras, IJCV, 1996)

- $F$ is the fundamental matrix. The progress is important: we can constrain the match without calibrating the cameras!
- It can be easily derived formally, by expressing everything in camera 2 coordinate frame:

$$
\lambda \mathbf{x}=K(R \mathbf{X}+T) \quad \lambda^{\prime} \mathbf{x}^{\prime}=K^{\prime} \mathbf{X}
$$

We remove the 5 unknowns $\mathbf{X}, \lambda$ and $\lambda^{\prime}$ from the system

$$
\lambda K^{-1} \mathbf{x}=\lambda^{\prime} R K^{\prime-1} \mathbf{x}^{\prime}+T \Rightarrow \lambda T \times\left(K^{-1} \mathbf{x}\right)=\lambda^{\prime}[T]_{\times} R K^{\prime-1} \mathbf{x}^{\prime}
$$

followed by scalar product with $K^{-1} \mathbf{x}$

## Anatomy of the fundamental matrix

## Glossary:

- $e=K T$ satisfies $e^{\top} F=0$, that is the left epipole
- $e^{\prime}=K^{\prime} R^{-1} T$ satisfies $F e^{\prime}=0$, that is the right epipole
- $F x^{\prime}$ is the epipolar line (in left image) associated to $x^{\prime}$
- $F^{\top} \mathbf{x}$ is the epipolar line (in right image) associated to $\mathbf{x}$
- Observe that if $T=0$ we get $F=0$, that is, no constraints: without displacement of optical center, no 3D information.
- The constraint is important: it is enough to look for the match of point $x$ along its associated epipolar line (1D search).

Theorem
A $3 \times 3$ matrix is a fundamental matrix iff it has rank 2

## Example

## RANSAC algorithm

## Singular Value Decomposition

Theorem (SVD)
Let $A$ be an $m \times n$ matrix. We can decompose $A$ as:

$$
A=U \Sigma V^{\top}=\sum_{i=1}^{\min (m, n)} \sigma_{i} U_{i} V_{i}^{\top}
$$

with $\Sigma$ diagonal $m \times n$ matrix and $\sigma_{i}=\Sigma_{i i}$,
$\sigma_{1} \geq \cdots \geq \sigma_{\min (m, n)} \geq 0, U \in O(m)$ and $V \in O(n)$.

- The rank of $A$ is the number of non-zero $\sigma_{i}$
- An orthonormal basis of the kernel of $A$ is composed of

$$
\left\{V_{i}: \sigma_{i}=0\right\} \cup\left\{V_{i}: i=m+1 \ldots n\right\}(\text { if } m<n)
$$

Theorem (Thin/compact SVD)

If $m \geq n, U m \times n$ and
$A=U\left(\begin{array}{lll}\sigma_{1} & & \\ & \ddots & \\ & & \sigma_{n}\end{array}\right) V^{\top}$

## Singular Value Decomposition

- Proof:

1. Orthonormal diagonalization of $A^{\top} A=V \Sigma^{\top} \Sigma V^{\top}$ (spectral theorem)
2. Write $U_{i}=A V_{i} / \sigma_{i}$ if $\sigma_{i} \neq 0$.
3. Check that $U_{i}^{\top} U_{j}=\delta_{i j}$.
4. Complement the $U_{i}$ by orthonormal vectors.
5. Check $A=U \Sigma V^{\top}$ by comparison on the basis formed by $\left\{V_{i}\right\}$.

- Implementation: efficient and numerically stable algorithm but As much as we dislike the use of black-box routines, we need to ask you to accept this one, since it would take us too far afield to cover its necessary background material here.

Numerical Recipes

- Algorithm: (i) Apply Givens rotations to reduce $A$ to bidiagonal form. (ii) Implicit QR algorithm to $A^{\top} A$ (see Appendix). Complexity: $O\left(m n^{2}\right)(m \geq n)$.

Essential and fundamental matrices

Singular Value Decomposition

Computation of E and F

RANSAC algorithm

## Computation of $F$

- The 8 point method (actually $8+$ ) is the simplest as it is linear.
- We write the epipolar constraint for the 8 correspondences

$$
\mathbf{x}_{\mathbf{i}}^{\top} F \mathbf{x}_{\mathbf{i}}^{\prime}=0 \Leftrightarrow A_{i}^{\top} f=0 \text { with } f=\left(\begin{array}{llllll}
f_{11} & f_{12} & f_{13} & f_{21} & \ldots & f_{33}
\end{array}\right)^{\top}
$$

- Each one is a linear equation in the unknown $f$.
- $f$ has 8 independent parameters, since scale is indifferent.
- We impose the constraint $\|f\|=1$ :

$$
\min _{f}\|A f\|^{2} \text { subject to }\|f\|^{2}=1 \text { with } A=\left(\begin{array}{c}
A_{1}^{\top} \\
\vdots \\
A_{8}^{\top}
\end{array}\right)
$$

- Solution: $f$ is an eigenvector of $A^{\top} A$ associated to its smallest eigenvalue $\left(=V_{9}\right.$ in SVD of $\left.A\right)$.
- Constraint: to enforce rank 2 of $F$, we compute its SVD, put $\sigma_{3}=0$ and recompose (orthogonal projection on rank-2 matrices wrt scalar product $\left.\langle A, B\rangle=\operatorname{Tr}\left(A^{\top} B\right)\right)$

## Computation of $F$

- Enforcing constraint det $F=0$ after minimization is not optimal.
- The 7 point method imposes that from the start.
- We get a linear system $A f=0$ with $A$ of size $7 \times 9$.
- Let $f_{1}, f_{2}$ be 2 free vectors of the kernel of $A$ (from SVD).
- Look for a solution $f_{1}+x f_{2}$ with $\operatorname{det} F=0$.
- $\operatorname{det}\left(F_{1}+x F_{2}\right)=P(x)$ with $P$ polynomial of degree 3 , we get 1 or 3 solutions.
- The main interest is not computing $F$ with fewer points (we have many more in general, which is anyway better for precision), but we have fewer chances of selecting false correspondences.
- By the way, how to ensure we did not incorporate bad correspondences in the equations?

## Normalization

- The 8 point algorithm "as is" yields very imprecise results
- Hartley (PAMI, 1997): In Defense of the Eight-Point Algorithm
- Explanation: the scales of coefficients of $F$ are very different. $F_{11}, F_{12}, F_{21}$ and $F_{22}$ are multiplied by $x_{i} x_{i}^{\prime}, x_{i} y_{i}^{\prime}, y_{i} x_{i}^{\prime}$ and $y_{i} y_{i}^{\prime}$, that can reach $10^{6}$. On the contrary, $F_{13}, F_{23}, F_{31}$ and $F_{32}$ are multiplied by $x_{i}, y_{i}, x_{i}^{\prime}$ and $y_{i}^{\prime}$ that are of order $10^{3}$. $F_{33}$ is multiplied by 1.
- The scales being so different, $A$ is badly conditioned.
- Solution: normalize points so that coordinates are of order 1.

$$
N=\left(\begin{array}{ccc}
10^{-3} & & \\
& 10^{-3} & \\
& & 1
\end{array}\right), \tilde{x}_{i}=N x_{i},{\tilde{x^{\prime}}}_{i}=N x_{i}^{\prime}
$$

- We find $\tilde{F}$ for points $\left(\tilde{x}_{i}, \tilde{x}^{\prime}{ }_{i}\right)$ then $F=N^{\top} \tilde{F} N$

## Computation of E

- E depends on 5 parameters ( 3 for $R+3$ for $T-1$ for scale)
- A $3 \times 3$ matrix $E$ is essential iff its singular values are 0 and two equal positive values. It can be written:

$$
2 E E^{\top} E-\operatorname{tr}\left(E E^{\top}\right) E=0, \quad \operatorname{det} E=0
$$

- 5 point algorithm (Nistér, PAMI, 2004)
- We have $A e=0, A$ of size $5 \times 9$, we get a solution of the form

$$
E=x X+y Y+z Z+W
$$

with $X, Y, Z, W$ a basis of the kernel of $A$ (SVD)

- The contraints yield 10 polynomial equations of degree 3 in $x, y, z$
- 1) Gauss pivot to eliminate terms of degree $2+$ in $x, y$, then $B(z)\left(\begin{array}{lll}x & y & 1\end{array}\right)^{\top}=0$, that is $\operatorname{det} B(z)=0$, degree 10 .

2) Gröbner bases. 3) $C(z)\left(\begin{array}{lllllll}1 & x & y & x^{2} & x y & \ldots & y^{3}\end{array}\right)^{\top}=0$ and $\operatorname{det} C(z)=0$ (Li\&Hartley, ICPR, 2006)

## Some useful rules of vector calculus

Essential and fundamental matrices

Singular Value Decomposition

Computation of E and F

RANSAC algorithm

## RANSAC algorithm

- How to solve a problem of parameter estimation in presence of outliers? This is the framework of robust estimation.
- Example: regression line of plane points $\left(x_{i}, y_{i}\right)$ with for certain $i$ bad data (not simply imprecise).
- Correct data are called inliers and incorrect outliers. Hypothesis: inliers are coherent while outliers are random.
- RANdom SAmple Consensus (Fishler\&Bolles, Com. of the ACM 1981):

1. Select $k$ samples out of $n, k$ being the minimal number to estimate uniquely a model.
2. Compute model and count samples among $n$ explained by model at precision $\sigma$.
3. If this number is larger than the most coherent one until now, keep it.
4. Back to 1 if we have iterations left.

- Example: $k=2$ for a plane regression line.

## RANSAC for fundamental matrix

- Choose $k=7$ or $k=8$
- Classify $\left(x_{i}, x_{i}^{\prime}\right)$ inlier/outlier as a function of the distance of $x_{i}^{\prime}$ to epipolar line associated to $x_{i}\left(F^{\top} x_{i}\right)$ :

$$
d\left(x_{i}^{\prime}, F^{\top} x_{i}\right)=\frac{\left|\left(F^{\top} x_{i}\right)_{1} u_{i}^{\prime}+\left(F^{\top} x_{i}\right)_{2} v_{i}^{\prime}+\left(F^{\top} x_{i}\right)_{3}\right|}{\sqrt{\left(F^{\top} x_{i}\right)_{1}^{2}+\left(F^{\top} x_{i}\right)_{2}^{2}}}
$$

- $k=7$ is better, because we have fewer chances to select an outlier. In that case, we can have 3 models by sample. We test the 3 models.

## RANSAC: number of iterations

- Suppose there are $m$ inliers.
- The probability of having an uncontaminated sample of $k$ inliers is $(m / n)^{k}$
- We require the probability that $N_{\text {iter }}$ samples are bad to be lower than $\beta=1 \%$ :

$$
\left(1-(m / n)^{k}\right)^{N_{\text {iter }}} \leq \beta
$$

- Therefore we need

$$
N_{\text {iter }} \geq\left\lceil\frac{\log \beta}{\log \left(1-(m / n)^{k}\right)}\right\rceil
$$

- $m$ is unknown, but a lower bound is the best number of inliers found so far.
- $\Rightarrow$ recompute $N_{\text {iter }}$ each time a better model is found.

## Conclusion

- Epipolar constraint:

1. Essential matrix $E$ (calibrated case)
2. Fundamental matrix $F$ (non calibrated case)

- $F$ can be computed with the 7 - or 8 -point algorithm.
- Computation of $E$ is much more complicated (5-point algorithm)
- Removing outliers through RANSAC algorithm.

## Appendix: QR algorithm for eigenvalue decomposition

Not to be confused with QR decomposition, but based on it. Let $A$ a square matrix. Iterate until convergence:

1. Set $A_{0}=A$.
2. Decompose $A_{k}=Q_{k} R_{k}$.
3. Set $A_{k+1}=R_{k} Q_{k}$.
$\left(A_{k}\right)_{k}$ converges to a triangular matrix $A_{\infty}$, eigenvalues of $A$ are read from the diagonal of $A_{\infty}$.
If $A$ is symmetric, all $A_{k}$ are also and so is $A_{\infty}$. Hence, it is diagonal.
Proof that $A_{k}$ and $A$ are similar:

$$
A_{k+1}=Q_{k}^{\top} Q_{k} R_{k} Q_{k}=Q_{k}^{\top} A_{k} Q_{k}
$$

## Rotation parameterization (Quaternions)

- $\operatorname{Span}(\mathbf{1}, \mathbf{i}, \mathbf{j}, \mathbf{k}) \subset \mathbb{C}^{2 \times 2}$ stable by multiplication as $\mathbb{R}$-vector space

$$
\mathbf{1}=l_{2} \quad \mathbf{i}=\left(\begin{array}{cc}
0 & -1 \\
1 & 0
\end{array}\right) \quad \mathbf{j}=\left(\begin{array}{cc}
i & 0 \\
0 & -i
\end{array}\right) \quad \mathbf{k}=\left(\begin{array}{cc}
0 & i \\
i & 0
\end{array}\right)
$$

with $\mathbf{i}^{2}=\mathbf{j}^{2}=\mathbf{k}^{2}=\mathbf{i} \mathbf{j} \mathbf{k}=-\mathbf{1}, \mathbf{i} \mathbf{j}=\mathbf{k}, \mathbf{j} \mathbf{k}=\mathbf{i}, \mathbf{k i}=\mathbf{j}$.
$-\mathbb{H}=\mathbb{R}^{4}$ with, noting $M(q)=q_{1} \mathbf{1}+q_{i} \mathbf{i}+q_{j} \mathbf{j}+q_{k} \mathbf{k}$,

$$
q_{3}=q_{1} q_{2} \Leftrightarrow M\left(q_{3}\right)=M\left(q_{1}\right) M\left(q_{2}\right)
$$

- Noting $\bar{q}=\left(q_{1},-q_{i},-q_{j},-q_{k}\right)$, $q \bar{q}=\left(\|q\|^{2}, 0,0,0\right) \Rightarrow q^{-1}=\bar{q} /\|q\|^{2}$.
- If $\|q\|=1$, write $c=\cos (\theta / 2)=q_{1}$,
$s=\sin (\theta / 2)=\left\|\left(q_{i}, q_{j}, q_{k}\right)\right\|$. The rotation $R$ around unit axis $\left(x_{0}, y_{0}, z_{0}\right)$ of angle $\theta$ is represented by $q=\left(c, s x_{0}, s y_{0}, s z_{0}\right)$.
- If $p=(x, y, z) \in \mathbb{R}^{3},(0, R p)=q(0, x, y, z) q^{-1}$.

## Practical session: RANSAC algorithm for $F$ computation

Objective: Fundamental matrix computation with RANSAC algorithm.

- Get initial program from the website.
- Write the core of function ComputeF. Use RANSAC algorithm (update $N_{\text {iter }}$ dynamically, but be careful of numerical problems with $m / n$ small), based on 8 -point algorithm. Solve the linear system estimating $F$ from 8 matches. Do not forget normalization! Hint: it is easier to use SVD with a square matrix. For that, add the 9th equation $0^{\top} f=0$.
- After RANSAC, refine resulting $F$ with least square minimization based on all inliers.
- Write the core of displayEpipolar: when user clicks, find in which image (left or right). Display this point and show associated epipolar line in other image.
